

# ECBM E6040 Neural Networks and Deep Learning

## Lecture #2: Elements of Linear Algebra and, Probability and Information Theory

Aurel A. Lazar

Columbia University  
Department of Electrical Engineering

January 26, 2016

# Outline of Part I

- 2 Summary of the Previous Lecture
  - Topics Covered
  - Learning Objectives

# Outline of Part II

- 3 Elements of Linear Algebra
  - Finite Dimensional Vector Spaces
  - Eigendecomposition and SVD
  - Principal Components Analysis

# Part I

## Review of Previous Lecture

# Topics Covered

- Logistics for ECBM E6040
- Introduction to Neural Networks and Deep Learning
- Programming Tools and Computing Resources

# Learning Objectives

- Neural Networks and Deep Learning: History, Role of GPUs, Expected Impact, Power and Limitations of Deep Learning
- Understanding how to use the Amazon Elastic Computing Cloud, Jupyter Notebooks and Git Repositories

## Part II

### Today's Lecture

# Finite Dimensional Vector Spaces

## Definition

A set  $E$  of elements is called a **vector space** (or a linear space, or a linear vector space) over  $\mathbb{C}$  if we have a function  $+$  on  $E \times E$  to  $E$  and a function  $\cdot$  on  $\mathbb{C} \times E$  to  $E$  such that for all  $x, y \in E$ :

$$x + y = y + x$$

$$(x + y) + z = x + (y + z)$$

$$x + 0 = x$$

$$\alpha(x + y) = \alpha x + \alpha y$$

$$(\alpha + \beta)x = \alpha x + \beta x$$

$$\alpha(\beta x) = (\alpha\beta)x$$

$$0 \cdot x = 0 \text{ and } 1 \cdot x = x$$

We call  $+$  the addition and  $\cdot$  the multiplication by scalars.

# Subspaces of a Vector Spaces

## Definition

A nonempty subset  $S$  of the vector space  $E$  is a **subspace** or a **linear manifold** if  $\alpha_1 x_1 + \alpha_2 x_2$  belongs to  $S$  whenever  $x_1$  &  $x_2$  do.

In what follows we shall assume for simplicity that  $\dim(E) = n$ .

## Definition

The span of  $S \subset E$  is the subspace of all linear combinations of vectors in  $S$ , i.e.,

$$\text{span}(S) = \left\{ \sum_{i=1}^n \alpha_i x_i \mid \alpha_i \in \mathbb{C}, x_i \in S \right\}.$$

# Basis

## Definition

A sequence  $\{e_k\}_{k=1}^n$  in  $E$  is a basis for  $E$  if the following two conditions are satisfied:

- (i)  $E = \text{span}\{e_k\}_{k=1}^n$ ;
- (ii)  $\{e_k\}_{k=1}^n$  is linearly independent, i.e., if  $\sum_{k=1}^n c_k e_k = 0$  for some scalar coefficients  $\{c_k\}_{k=1}^n$ , then  $c_k = 0$  for all  $k, k = 1, \dots, n$ .

## Vectors in $E = \mathbb{R}^n$

Consider the vectors  $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$  and  $c, d \in \mathbb{R}$ . Then any linear combination  $c\mathbf{x} + d\mathbf{y} \in \mathbb{R}^n$ .

### Definition (Dot Product)

The dot product or inner product of  $\mathbf{x} = (x_1, x_2, \dots, x_n)$  and  $\mathbf{y} = (y_1, y_2, \dots, y_n)$  is given by

$$\langle \mathbf{x}, \mathbf{y} \rangle = \mathbf{x}^T \cdot \mathbf{y} = \sum_{k=1}^n x_k y_k.$$

### Definition (Length or Norm)

The length or norm of a vector  $\mathbf{x}$  is given by

$$\|\mathbf{x}\| = \sqrt{\mathbf{x}^T \cdot \mathbf{x}}.$$

# Eigenvalues and Eigenvectors

Let  $\mathbf{A}$  be an  $(n, n)$  **square** matrix. If

$$\mathbf{Ax} = \lambda\mathbf{x}$$

$\mathbf{x}$  is said to be an eigenvector of  $A$  and  $\lambda$  an eigenvalue.

## Theorem

*The eigenvalues are the solution of the equation*

$$\det(\mathbf{A} - \lambda\mathbf{I}) = 0$$

*and the eigenvectors are in the nullspace of  $(\mathbf{A} - \lambda\mathbf{I})$ .*

# Diagonalizing a Matrix

Assume that the matrix  $\mathbf{A}$  has  $n$  **linearly independent eigenvectors**  $\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_n$ . Let  $\mathbf{S}$  be the matrix defined by  $\mathbf{S} = [\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_n]$ .

## Theorem

$$\mathbf{S}^{-1}\mathbf{A}\mathbf{S} = \mathbf{\Lambda} = \begin{bmatrix} \lambda_1 & 0 & \dots & 0 \\ 0 & \lambda_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \lambda_n \end{bmatrix}$$

or

$$\mathbf{A} = \mathbf{S}\mathbf{\Lambda}\mathbf{S}^{-1}.$$

## Remark

***Invertibility** is concerned with eigenvalues. **Diagonalizability** is concerned with eigenvectors.*

# Symmetric Matrices

Assume that  $A = A^T$ , where  $T$  denotes the transpose. Then

- $A$  has only real eigenvalues;
- The eigenvectors can be chosen to be orthonormal.

## Theorem (Spectral Theorem)

*Every symmetric matrix  $\mathbf{A}$  can be written as*

$$\mathbf{A} = \mathbf{Q}\mathbf{\Lambda}\mathbf{Q}^T$$

*with  $\mathbf{\Lambda}$  having real eigenvalues,  $\mathbf{Q}$  orthonormal eigenvectors and  $\mathbf{Q}^{-1} = \mathbf{Q}^T$ .*

# Bases and Singular Value Decomposition (SVD)

Let  $A$  be an  $(m, n)$  matrix, square or **rectangle**. Recall that if  $A$  is a diagonalizable square matrix the input and output bases are eigenvectors of  $A$  and

$$S^{-1}AS = \Lambda.$$

However, this factorization will not work if the matrix is non-diagonalizable (eigenvectors dependent) or  $m \neq n$ .

We will use a different method of diagonalization. Assume that the row space of  $A$  is  $r$ -dimensional in  $\mathbb{R}^n$ . Its column space is also  $r$ -dimensional in  $\mathbb{R}^m$ . For SVD, the input and output bases are eigenvectors of the symmetric matrices  $AA^T$  and  $A^T A$  (both of rank  $r$ ) and

$$U^{-1}AV = \Sigma.$$

$AA^T$  and  $A^T A$  are  $(m, m)$  and  $(n, n)$ , respectively.

# Singular Value Decomposition

We consider the **orthonormal basis**  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n$  for the **row space** (in  $\mathbb{R}^n$ ), and the **orthonormal basis**  $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_m$  for the **column space** (in  $\mathbb{R}^m$ ). We require non-negative numbers  $\sigma_i$  such that

$$\mathbf{A}\mathbf{v}_i = \sigma_i\mathbf{u}_i, \text{ and } \mathbf{A}^T\mathbf{u}_i = \sigma_i\mathbf{v}_i, i = 1, 2, \dots, r$$

that is,  $\mathbf{A}\mathbf{v}_i$  is in the direction of  $\mathbf{u}_i$ . In matrix form this becomes

$$\mathbf{A}\mathbf{V} = \mathbf{U}\mathbf{\Sigma} \quad \text{or} \quad \mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^T,$$

since by orthonormality  $\mathbf{V}^{-1} = \mathbf{V}^T$ . Here  $\mathbf{\Sigma}$  is an  $(m, n)$  diagonal matrix with elements  $\sigma_i$  on the diagonal,  $\mathbf{U}$  is an  $(m, m)$  matrix and  $\mathbf{V}$  is an  $(n, n)$  matrix.

# Singular Value Decomposition (cont'd)

Now note that

$$\mathbf{A}^T \mathbf{A} = (\mathbf{U} \mathbf{\Sigma} \mathbf{V}^T)^T (\mathbf{U} \mathbf{\Sigma} \mathbf{V}^T) = \mathbf{V} \mathbf{\Sigma}^T \mathbf{\Sigma} \mathbf{V}^T$$

or

$$\mathbf{A}^T \mathbf{A} = \mathbf{V} \begin{bmatrix} \sigma_1^2 & 0 & \dots & 0 & \dots & 0 \\ 0 & \sigma_2^2 & \dots & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \sigma_r^2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 0 & \dots & 0 \end{bmatrix} \mathbf{V}^T.$$

Similarly

$$\mathbf{A} \mathbf{A}^T = \mathbf{U} \mathbf{\Sigma} \mathbf{\Sigma}^T \mathbf{U}^T.$$

## Singular Value Decomposition (cont'd)

Note that the diagonal matrix  $\Sigma\Sigma^T$  is an  $(m, m)$  matrix and  $\Sigma^T\Sigma$  is an  $(n, n)$  matrix.

The singular values  $\sigma_1^2, \sigma_2^2, \dots, \sigma_r^2$  are the eigenvalues and the columns of  $\mathbf{V}$  are the eigenvectors of  $\mathbf{A}^T\mathbf{A}$ .

The singular values  $\sigma_1^2, \sigma_2^2, \dots, \sigma_r^2$  are the eigenvalues and the columns of  $\mathbf{U}$  are the eigenvectors of  $\mathbf{A}\mathbf{A}^T$ .

Note that  $r$  is the rank of the matrix  $\mathbf{A}$ .

Finally, note that all this works because  $\mathbf{A}\mathbf{A}^T$  and  $\mathbf{A}^T\mathbf{A}$  are  $(m, m)$  and  $(n, n)$  **symmetric matrices**, respectively.

# Change of Basis

Recall that by choosing good bases

$$\mathbf{A}\mathbf{v}_i = \sigma_i\mathbf{u}_i,$$

where  $\mathbf{v}_i \in \mathbb{R}^n$  and  $\mathbf{u}_i \in \mathbb{R}^m$ . Thus,  $\mathbf{A}$  takes  $\mathbf{v}_i$  in the row space and maps into  $\sigma_i\mathbf{u}_i$  in the column space. We are interested in doing the opposite now, i.e.,

$$\mathbf{A}^{-1}\mathbf{u}_i = \mathbf{v}_i/\sigma_i.$$

However,  $\mathbf{A}$  is an  $(m, n)$  matrix and therefore it does not have a proper inverse. We answer this question by essentially constructing an inverse on a subset of vectors.

# Pseudo-Inverse

The **pseudo-inverse** is given by

$$\mathbf{A}^+ = \mathbf{V}\mathbf{\Sigma}^+\mathbf{U}^T$$

or

$$\mathbf{A}^+ = [\mathbf{v}_1 \dots \mathbf{v}_r \dots \mathbf{v}_n] \begin{bmatrix} \sigma_1^{-1} & 0 & \dots & 0 & \dots & 0 \\ 0 & \sigma_2^{-1} & \dots & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \sigma_r^{-1} & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 0 & \dots & 0 \end{bmatrix} [\mathbf{u}_1 \dots \mathbf{u}_r \dots \mathbf{u}_m]$$

## Pseudo-Inverse (cont'd)

The pseudo-inverse  $\mathbf{A}^+$  is an  $(n, m)$  matrix. If  $\mathbf{A}^{-1}$  exists, then

$$\mathbf{A}^+ = \mathbf{A}^{-1} = (\mathbf{U}\Sigma\mathbf{V}^T)^{-1} = (\mathbf{V}\Sigma^{-1}\mathbf{U}^T).$$

Notice also that,

$$\mathbf{A}^+\mathbf{u}_i = \mathbf{v}_i/\sigma_i \quad \text{for } i \leq r \quad \text{and} \quad \mathbf{A}^+\mathbf{u}_i = 0 \quad \text{for } i > r.$$

### Lemma

$\mathbf{A}\mathbf{A}^+$  is the *projection matrix* onto the column space of  $\mathbf{A}$ .  $\mathbf{A}^+\mathbf{A}$  is the *projection matrix* onto the row space of  $\mathbf{A}$  and

$$\mathbf{A}\mathbf{A}^+ = \mathbf{U}\Sigma\Sigma^+\mathbf{U}^T, \quad \mathbf{A}^+\mathbf{A} = \mathbf{V}\Sigma^+\Sigma\mathbf{V}^T,$$

where  $\mathbf{u}, \mathbf{v}$  are the matrices  $\mathbf{U}, \mathbf{V}$  restricted to their first  $r$  columns.

## Pseudo-Inverse (cont'd)

A projection matrix  $\mathbf{P}$  has the property that  $\mathbf{P}^2 = \mathbf{P}$ . Clearly

$$(\mathbf{A}\mathbf{A}^+)^2 = \mathbf{U}\Sigma\Sigma^+\mathbf{U}^T\mathbf{U}\Sigma\Sigma^+\mathbf{U}^T = \mathbf{U}(\Sigma\Sigma^+)^2\mathbf{U}^T = \mathbf{U}\Sigma\Sigma^+\mathbf{U}^T$$

and

$$(\mathbf{A}^+\mathbf{A})^2 = \mathbf{V}\Sigma^+\Sigma\mathbf{V}^T\mathbf{V}\Sigma^+\Sigma\mathbf{V}^T = \mathbf{V}(\Sigma^+\Sigma)^2\mathbf{V}^T = \mathbf{V}\Sigma^+\Sigma\mathbf{V}^T.$$

Furthermore,

- (i)  $\mathbf{A}\mathbf{A}^+\mathbf{A} = \mathbf{A}$  ;
- (ii)  $\mathbf{A}^+\mathbf{A}\mathbf{A}^+ = \mathbf{A}^+$  ;
- (iii)  $(\mathbf{A}\mathbf{A}^+)^T = \mathbf{A}\mathbf{A}^+$  ;
- (iv)  $(\mathbf{A}^+\mathbf{A})^T = \mathbf{A}^+\mathbf{A}$  ;

## Example

Let  $\mathbf{A} = [1, 1]$ . Then

- $\mathbf{A}^T \mathbf{A} = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$ .
- $\mathbf{A}^T \mathbf{A}$  has eigenvalues  $\sigma_1^2 = 2$  and  $\sigma_2^2 = 0$  with corresponding eigenvectors  $\mathbf{v}_1 = [\sqrt{2}/2, \sqrt{2}/2]^T$  and  $\mathbf{v}_2 = [-\sqrt{2}/2, \sqrt{2}/2]^T$ , respectively.
- $\mathbf{A} \mathbf{A}^T = 2$  with eigenvalue  $\sigma_1^2 = 2$  and eigenvector  $\mathbf{u}_1 = 1$ .
- The SVD and pseudoinverse of  $\mathbf{A}$  are given by

$$\mathbf{A} = 1[\sqrt{2}, 0] \begin{bmatrix} \sqrt{2}/2 & -\sqrt{2}/2 \\ \sqrt{2}/2 & \sqrt{2}/2 \end{bmatrix}^T$$
$$\mathbf{A}^+ = \begin{bmatrix} \sqrt{2}/2 & -\sqrt{2}/2 \\ \sqrt{2}/2 & \sqrt{2}/2 \end{bmatrix} \begin{bmatrix} \sqrt{2}/2 \\ 0 \end{bmatrix} 1 = \begin{bmatrix} 0.5 \\ 0.5 \end{bmatrix}$$

# Principal Component Analysis

## A Simple Machine Learning Algorithm

Assume we have a collection of  $m$  points

$$\{\mathbf{x}^1, \mathbf{x}^2, \dots, \mathbf{x}^m\} \in \mathbb{R}^n.$$

We would like to reduce the storage requirements without losing too much precision.

Approach: Each point  $\mathbf{x}^i \in \mathbb{R}^n$  is mapped into a code vector  $\mathbf{c}^i \in \mathbb{R}^l$  with  $l < n$ . To make the decoder simple, a matrix  $\mathbf{D} \in \mathbb{R}^{n \times l}$  is chosen and  $\mathbf{D}\mathbf{c}$  is used to map back the code into  $\mathbb{R}^n$ .

# The Optimal Code

To keep the encoding problem tractable, PCA constrains the **columns** of **D** to be **orthogonal** to each other. In addition, we shall assume that **the columns of D have unit norm**.

## Lemma

Let  $\mathbf{c}^*$  denote the optimal code for each input point  $\mathbf{x}$ , i.e.,

$$\mathbf{c}^* = \arg \min_{\mathbf{c}} \|\mathbf{x} - \mathbf{D}\mathbf{c}\|_2.$$

We have

$$\mathbf{c}^* = \mathbf{D}^T \mathbf{x}.$$

# The Optimal Code (cont'd)

## Proof

Note that

$$\mathbf{c}^* = \arg \min_{\mathbf{c}} \|\mathbf{x} - \mathbf{D}\mathbf{c}\|_2^2.$$

Now since

$$\|\mathbf{x} - \mathbf{D}\mathbf{c}\|_2^2 = (\mathbf{x} - \mathbf{D}\mathbf{c})^T (\mathbf{x} - \mathbf{D}\mathbf{c}) = \mathbf{x}^T \mathbf{x} - \mathbf{c}^T \mathbf{D}^T \mathbf{x} - \mathbf{x}^T \mathbf{D}\mathbf{c} + \mathbf{c}^T \mathbf{D}^T \mathbf{D}\mathbf{c},$$

we obtain

$$\|\mathbf{x} - \mathbf{D}\mathbf{c}\|_2^2 = \mathbf{x}^T \mathbf{x} - 2\mathbf{x}^T \mathbf{D}\mathbf{c} + \mathbf{c}^T \mathbf{I}_I \mathbf{c},$$

and, therefore,

$$\mathbf{c}^* = \arg \min_{\mathbf{c}} [-2\mathbf{x}^T \mathbf{D}\mathbf{c} + \mathbf{c}^T \mathbf{c}].$$

# The Optimal Code (cont'd)

## Proof (cont'd)

This is a simple optimization problem that can be solved by computing the solution of the gradient equation:

$$\nabla \mathbf{c}[-2\mathbf{x}^T \mathbf{D} \mathbf{c} + \mathbf{c}^T \mathbf{c}] = \mathbf{0},$$

i.e.,

$$-2\mathbf{D}^T \mathbf{x} + 2\mathbf{c} = \mathbf{0}$$

or

$$\mathbf{c} = \mathbf{D}^T \mathbf{x}.$$

# PCA Reconstruction

## Finding the $\mathbf{D}$ Matrix

The PCA reconstruction operation amounts to computing  $\mathbf{D}\mathbf{D}^T\mathbf{x}$ . We now need to find an optimal encoding matrix  $\mathbf{D}$ .

### Lemma

*The decoding matrix  $\mathbf{D}$  minimizes the Frobenius norm*

$$\mathbf{D}^* = \arg \min_{\mathbf{D}} \sqrt{\sum_{i,j} [x_j^i - (\mathbf{D}\mathbf{D}^T\mathbf{x}^i)_j]^2}$$

*subject to  $\mathbf{D}^T\mathbf{D} = \mathbf{I}_l$  is given by the  $l$  eigenvectors corresponding to the largest eigenvalues of  $\mathbf{X}^T\mathbf{X}$ . Here,  $\mathbf{X} \in \mathbb{R}^{m \times n}$  is the matrix defined by stacking all the vectors describing the  $m$  points such that  $\mathbf{X}_{i,:} = (\mathbf{x}^i)^T$ .*

# Deriving the $\mathbf{D}$ Matrix

## Proof

We derive the algorithm for finding  $\mathbf{D}^*$  for the case  $l = 1$ . The case  $l > 1$  can be obtained via induction. Here  $\mathbf{D} = \mathbf{d}$ , where  $\mathbf{d}$  is a single vector. The minimization problem becomes

$$\mathbf{d}^* = \arg \min_{\mathbf{d}} \sum_i \|\mathbf{x}^i - \mathbf{d}\mathbf{d}^T \mathbf{x}^i\|_2^2 = \arg \min_{\mathbf{d}} \sum_i \|\mathbf{x}^i - \mathbf{d}^T \mathbf{x}^i \mathbf{d}\|_2^2$$

or

$$\mathbf{d}^* = \arg \min_{\mathbf{d}} \sum_i \|\mathbf{x}^i - (\mathbf{x}^i)^T \mathbf{d} \mathbf{d}\|_2^2,$$

subject to  $\|\mathbf{d}\|_2 = 1$ . With  $\mathbf{X}_i = (\mathbf{x}^i)^T$  the above minimization problem can be written in compact form as

$$\mathbf{d}^* = \arg \min_{\mathbf{d}} \|\mathbf{X} - \mathbf{X} \mathbf{d} \mathbf{d}^T\|_F^2$$

subject to  $\mathbf{d}^T \mathbf{d} = 1$ .

# Deriving the **D** Matrix (cont'd)

## Proof

Now

$$\|\mathbf{X} - \mathbf{X}\mathbf{d}\mathbf{d}^T\|_F^2 = \text{Tr}[(\mathbf{X} - \mathbf{X}\mathbf{d}\mathbf{d}^T)^T(\mathbf{X} - \mathbf{X}\mathbf{d}\mathbf{d}^T)]$$

by the alternate definition of the Frobenius norm and the RHS can be written as

$$\begin{aligned} & \text{Tr}(\mathbf{X}^T\mathbf{X} - \mathbf{X}^T\mathbf{X}\mathbf{d}\mathbf{d}^T - \mathbf{d}\mathbf{d}^T\mathbf{X}^T\mathbf{X} + \mathbf{d}\mathbf{d}^T\mathbf{X}^T\mathbf{X}\mathbf{d}\mathbf{d}^T) = \\ &= \text{Tr}(\mathbf{X}^T\mathbf{X}) - \text{Tr}(\mathbf{X}^T\mathbf{X}\mathbf{d}\mathbf{d}^T) - \text{Tr}(\mathbf{d}\mathbf{d}^T\mathbf{X}^T\mathbf{X}) + \text{Tr}(\mathbf{d}\mathbf{d}^T\mathbf{X}^T\mathbf{X}\mathbf{d}\mathbf{d}^T) \\ &= \text{Tr}(\mathbf{X}^T\mathbf{X}) - 2\text{Tr}(\mathbf{X}^T\mathbf{X}\mathbf{d}\mathbf{d}^T) + \text{Tr}(\mathbf{d}\mathbf{d}^T\mathbf{X}^T\mathbf{X}\mathbf{d}\mathbf{d}^T), \end{aligned}$$

because we can cycle the order of the matrices inside the trace.

# Deriving the **D** Matrix (cont'd)

## Proof

The minimization problem can be now written as

$$\begin{aligned} \arg \min_{\mathbf{d}} \quad & -2 \operatorname{Tr}(\mathbf{X}^T \mathbf{X} \mathbf{d} \mathbf{d}^T) + \operatorname{Tr}(\mathbf{d} \mathbf{d}^T \mathbf{X}^T \mathbf{X} \mathbf{d} \mathbf{d}^T) = \\ & = \arg \min_{\mathbf{d}} \quad -2 \operatorname{Tr}(\mathbf{X}^T \mathbf{X} \mathbf{d} \mathbf{d}^T) + \operatorname{Tr}(\mathbf{X}^T \mathbf{X} \mathbf{d} \mathbf{d}^T \mathbf{d} \mathbf{d}^T) \end{aligned}$$

because we can cycle the order the matrices inside a trace (again!).  
With the constraint  $\mathbf{d}^T \mathbf{d} = 1$  the minimization is reduced to

$$\arg \min_{\mathbf{d}} \quad -\operatorname{Tr}(\mathbf{X}^T \mathbf{X} \mathbf{d} \mathbf{d}^T) = \arg \max_{\mathbf{d}} \quad \operatorname{Tr}(\mathbf{X}^T \mathbf{X} \mathbf{d} \mathbf{d}^T)$$

or finally

$$\arg \max_{\mathbf{d}} \quad \operatorname{Tr}(\mathbf{d}^T \mathbf{X}^T \mathbf{X} \mathbf{d})$$

subject to  $\mathbf{d}^T \mathbf{d} = 1$ .

# Deriving the **D** Matrix (cont'd)

## Proof

The optimization problem

$$\arg \max_{\mathbf{d}} \text{Tr}(\mathbf{d}^T \mathbf{X}^T \mathbf{X} \mathbf{d})$$

subject to  $\mathbf{d}^T \mathbf{d} = 1$  can be solved using eigendecomposition. The optimal  $\mathbf{d}$  is given by the eigenvector of  $\mathbf{X}^T \mathbf{X}$  corresponding to the largest eigenvalue.  $\square$
